
IS 2610: Data Structures

Priority Queue, Heapsort, Searching

March 15, 2004

Priority Queues

- Applications require that we process records with keys in order
 - Collect records
 - Process one with largest key
 - Maybe collect more records
 - Applications
 - Simulation systems (event times)
 - Scheduling (priorities)
 - Priority queue: A data structure of items with keys that support two basic operations: Insert a new item; Delete the item with the largest key
-

Priority Queue

- Build and maintain the following operations
 - Construct the queue
 - Insert a new item
 - Delete the maximum item
 - Change the priority of an arbitrary specified item
 - Delete an arbitrary specified item
 - Join two priority queues into one large one
-

Priority Queue: Elementary operations

```
void PQinit(int);  
int PQempty();  
void PQinsert(Item);  
Item PQdelmax();
```

```
#include <stdlib.h>  
#include "Item.h"  
static Item *pq;  
static int N;  
void PQinit(int maxN)  
    { pq = malloc(maxN*sizeof(Item)); N = 0; }  
int PQempty()  
    { return N == 0; }  
void PQinsert(Item v)  
    { pq[N++] = v; }  
Item PQdelmax()  
    { int j, max = 0;  
      for (j = 1; j < N; j++)  
          if (less(pq[max], pq[j])) max = j;  
      exch(pq[max], pq[N-1]);  
      return pq[--N];  
    }
```

Heap Data Structure

- Def 9.2

- A tree is heap-ordered if the key in each node is larger than or equal to the keys in all of that node's children (if any). Equivalently, the key in each node of a heap-ordered tree is smaller than or equal to the key in that node's parent (if any)

- Property 9.1

- No node in a heap-ordered tree has a key larger than the key at the root.

- Heap can efficiently support the basic priority-queue operations

Heap Data Structure

■ Def 9.2

- A heap is a set of nodes with keys arranged in a complete heap-ordered binary tree, [represented as an array].

■ A complete tree allows using a compact array representation

- The parent of node i is in position $\lfloor i/2 \rfloor$
 - The two children of the node i are in positions $2i$ and $2i + 1$.
 - Disadvantage of using arrays?
-

Algorithms on Heaps

■ Heapifying

- Modify heap to violate the heap condition
 - Add new element
 - Change the priority
- Restructure heap to restore the heap condition

Priority of child becomes greater

Bottom-up heapify

- First exchange T and R
- Then exchange T and S

```
fixUp(Item a[], int k)
{
  while (k > 1 && less(a[k/2], a[k]))
  { exch(a[k], a[k/2]); k = k/2; }
}
```

Top-down heapify

- Exchange with the larger child

```
fixDown(Item a[], int k, int N)
{
  int j;
  while (2*k <= N)
  {
    j = 2*k;
    if (j < N && less(a[j], a[j+1])) j++;
    if (!less(a[k], a[j])) break;
    exch(a[k], a[j]); k = j;
  }
}
```

Priority of parent becomes smaller

Heap-based priority Queue

■ Property 9.2

- Insert requires no more than $\lg n$
 - one comparison at each level
- Delete maximum requires no more than $2 \lg n$
 - two comparisons at each level

```
#include <stdlib.h>
#include "Item.h"
static Item *pq;
static int N;
void PQinit(int maxN)
{ pq = malloc((maxN+1)*sizeof(Item)); N = 0; }
int PQempty()
{ return N == 0; }
void PQinsert(Item v)
{ pq[++N] = v; fixUp(pq, N); }
Item PQdelmax()
{
    exch(pq[1], pq[N]);
    fixDown(pq, 1, N-1);
    return pq[N--];
}
```

Sorting with a priority Queue

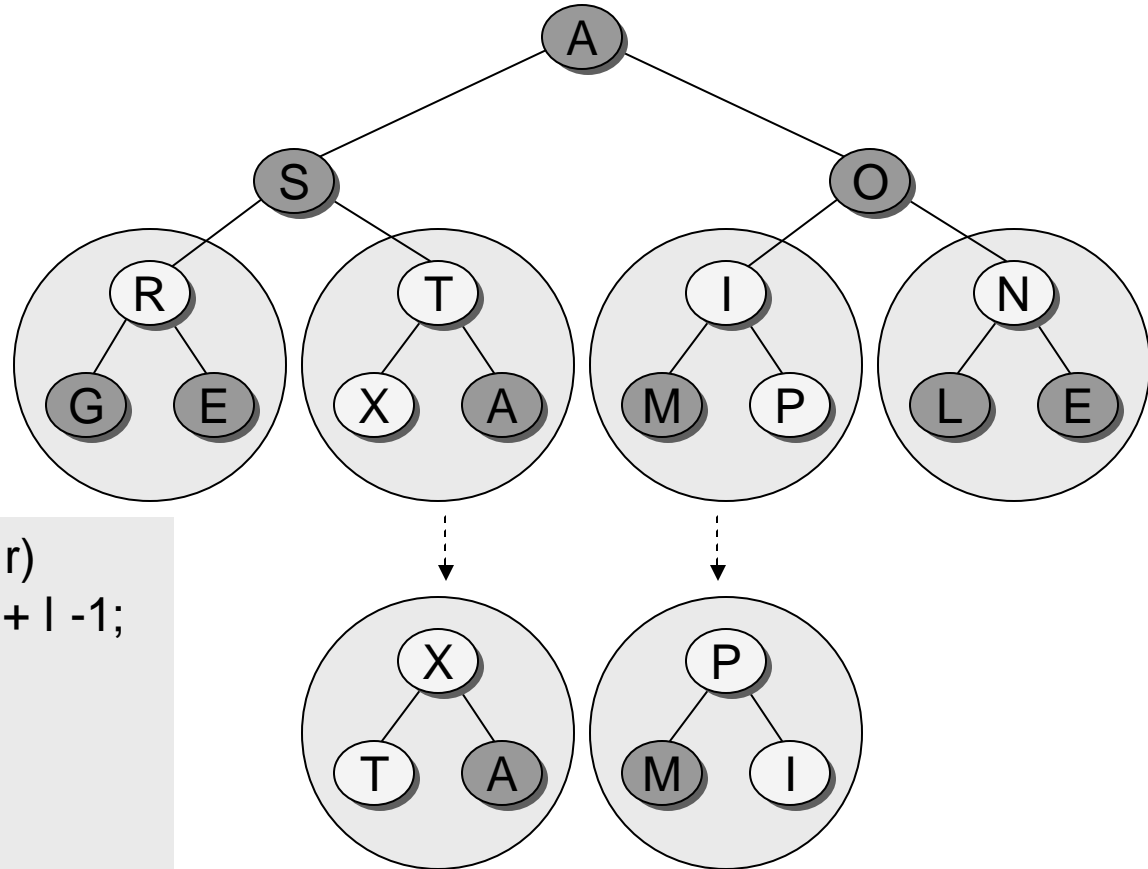

- Use PQinsert to put all the elements on the priority queue
- Use PQdelmax to remove them in decreasing order

Heap construction takes
 $< n \lg n$

```
void PQsort(Item a[], int l, int r)
{ int k;
  PQinit();
  for (k = l; k <= r; k++) PQinsert(a[k]);
  for (k = r; k >= l; k--) a[k] = PQdelmax();
}
```

Bottom-up Heap

- Right to left
- Bottom-up

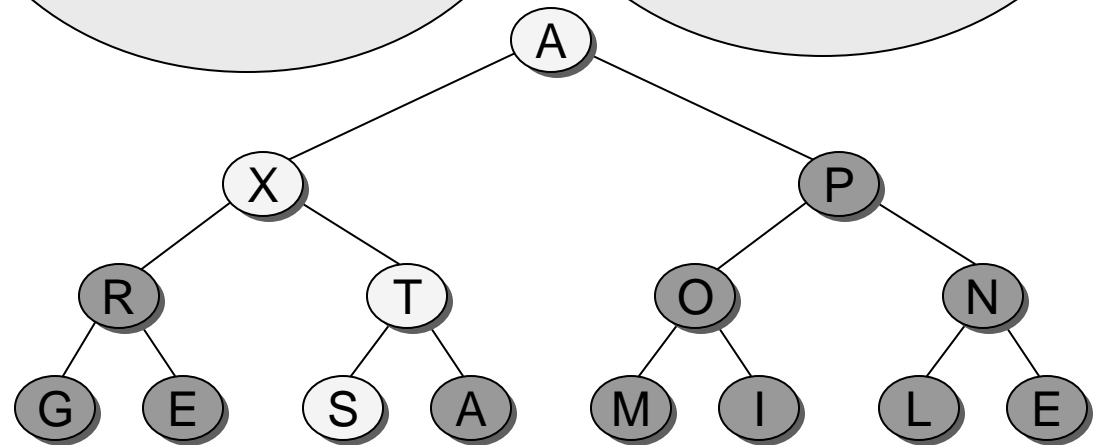

```
void heapsort(Item a[], int l, int r)
{ int k, N = r-l+1; Item* pq = a + l - 1;
  for (k = N/2; k >= 1; k--)
    fixDown(pq, k, N);
  while (N > 1)
    { exch(pq[1], pq[N]);
      fixDown(pq, 1, --N); }
}
```

Bottom-up Heap

- Note: most nodes are at the bottom

- Bottom up heap construction takes linear time

Radix Sort

- Decompose keys into pieces
 - Binary numbers are sequence of bytes
 - Strings are sequence of characters
 - Decimal number are sequence of digits
 - Radix sort:
 - Sorting methods built on processing numbers one piece at a time
 - Treat keys as numbers represented in base R and work with individual digits
 - $R = 10$ in many applications where keys are 5- to 10-digit decimal numbers
 - Example: postal code, telephone numbers, SSN
-

Radix Sort

- If keys are integers
 - Can use $R = 2$, or a multiple of 2
 - If keys are strings of characters
 - Can use $R = 128$ or 256 (aligns with a byte)
 - Radix sort is based on the abstract operation
 - Extract the i^{th} digit from a key
 - Two approaches to radix sort
 - Most-significant-digit (MSD) radix sorts (left-to-right)
 - Least-significant-digit (LSD) radix sorts (right-to-left)
-

Bits, Bytes and Word

- The key to understanding Radix sorts is to recognize that
 - Computers generally are built to process bits in groups called machine words (groups of bytes)
 - Sort keys are commonly organized as byte sequences
 - Small byte sequence can also serve as array indices or machine addresses
 - Hence an abstraction can be used
-

Bits, Bytes and Word

- Def: A byte is a fixed-length sequence of bits; a string is a variable-length sequence of bytes; a word is a fixed-length sequence of bytes

```
#define bitsword 32
#define bitsbyte 8
#define bytesword 4
#define R (1 << bitsbyte)
```

```
#define digit(A, B)
    (((A) >> (bitsword-((B)+1)*bitsbyte)) & (R-1))
```

- `digit(A, 2)??`

```
// Another possibility
#define digit(A, B) A[B]
```

Binary Quicksort

- Partition a file based on leading bits
- Sort the sub-files recursively

```
quicksortB(int a[], int l, int r, int w)
{ int i = l, j = r;
  if (r <= l || w > bitsword) return;
  while (j != i)
  {
    while (digit(a[i], w) == 0 && (i < j)) i++;
    while (digit(a[j], w) == 1 && (j > i)) j--;
    exch(a[i], a[j]);
  }
  if (digit(a[r], w) == 0) j++;
  quicksortB(a, l, j-1, w+1);
  quicksortB(a, j, r, w+1);
}
void sort(Item a[], int l, int r)
{
  quicksortB(a, l, r, 0);
}
```

Binary Quicksort

■ 001	■ 001	■ <u>001</u>	■ <u>001</u>
■ 111	■ 010	■ 010	■ 010
■ 011	■ <u>011</u>	■ 011	■ 011
■ 100	■ 100	■ 100	■ 100
■ 101	■ 101	■ <u>101</u>	■ <u>101</u>
■ 010	■ 111	■ 111	■ 111

MSD Radix Sort

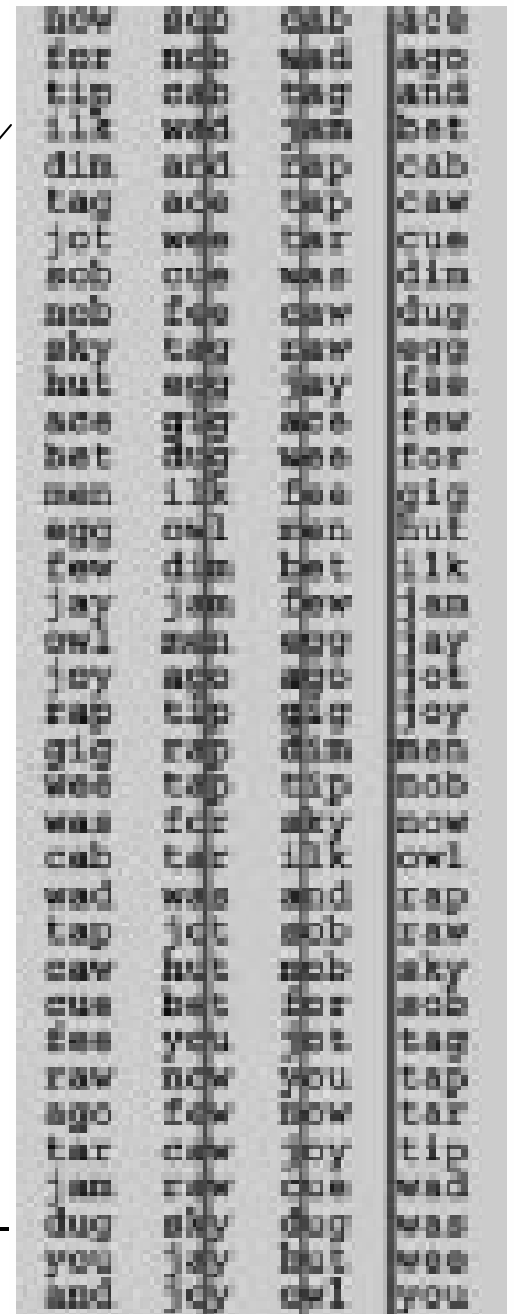

- Binary Quicksort is a MSD with $R = 2$;
- For general R , we will partition the array into R different bins/buckets

Symbol Table

- A symbol table is a data structure of items with keys that supports two basic operations: *insert* a new item, and *return* an item with a given key
 - Examples:
 - Account information in banks
 - Airline reservations
-

Symbol Table ADT

- Key operations
 - Insert a new item
 - Search for an item with a given key
 - Delete a specified item
 - Select the k^{th} smallest item
 - Sort the symbol table
 - Join two symbol tables

```
void STinit(int);  
int STcount();  
void STinsert(Item);  
Item STsearch(Key);  
void STdelete(Item);  
Item STselect(int);  
void STsort(void (*visit)(Item));
```

Key-indexed ST

- Simplest search algorithm is based on storing items in an array, indexed by the keys

```
static Item *st;
static int M = maxKey;
void STinit(int maxN)
{ int i;
  st = malloc((M+1)*sizeof(Item));
  for (i = 0; i <= M; i++) st[i] = NULLitem;
}
```

```
int STcount()
{ int i, N = 0;
  for (i = 0; i < M; i++)
    if (st[i] != NULLitem) N++;
  return N;
}

void STinsert(Item item)
{ st[key(item)] = item; }

Item STsearch(Key v)
{ return st[v]; }

void STdelete(Item item)
{ st[key(item)] = NULLitem; }

Item STselect(int k)
{ int i;
  for (i = 0; i < M; i++)
    if (st[i] != NULLitem)
      if (k-- == 0) return st[i];
}

void STsort(void (*visit)(Item))
{ int i;
  for (i = 0; i < M; i++)
    if (st[i] != NULLitem) visit(st[i]);
}
```

Sequential Search based ST

- When a new item is inserted, we put it into the array by moving the larger elements over one position (as in insertion sort)
 - To search for an element
 - Look through the array sequentially
 - If we encounter a key larger than the search key – we report an error
-

Binary Search

- Divide and conquer methodology
 - Divide the items into two parts
 - Determine which part the search key belongs to and concentrate on that part
 - Keep the items sorted
 - Use the indices to delimit the part searched.

```
Item search(int l, int r, Key v)
{ int m = (l+r)/2;
  if (l > r) return NULLitem;
  if eq(v, key(st[m])) return st[m];
  if (l == r) return NULLitem;
  if less(v, key(st[m]))
    return search(l, m-1, v);
  else return search(m+1, r, v);
}
Item STsearch(Key v)
{ return search(0, N-1, v); }
```
